

Photosynthesis - Exam Revision Notes

Photosynthesis is the process by which green plants, algae, and some bacteria convert light energy into chemical energy stored in glucose.

Key inputs: CO₂, H₂O, light energy.

Key outputs: glucose, oxygen.

Light-dependent reactions occur in thylakoid membranes. The Calvin cycle occurs in the stroma (carbon fixation, reduction, regeneration of RuBP).

Exam tip: photosynthesis and cellular respiration are complementary processes.

Common trap: confuse light reactions (thylakoid) with Calvin cycle (stroma).
